mats/charts, 10-by-10 grids, decimal squares, base-ten blocks, meter sticks, number lines, and money.

- Proper fractions, improper fractions, and mixed numbers are terms often used to describe fractions. A proper fraction is a fraction whose numerator is less than the denominator. An improper fraction is a fraction whose numerator is equal to or greater than the denominator. An improper fraction may be expressed as a mixed number. A mixed number is written with two parts: a whole number and a proper fraction (e.g., $3\frac{5}{8}$).
- An amount less than one whole can be represented by a fraction or by an equivalent decimal.
- Base-ten models (e.g., 10-by-10 grids, meter sticks, number lines, decimal squares, money) demonstrate the relationship between fractions and decimals.

<table>
<thead>
<tr>
<th>Essential Questions</th>
</tr>
</thead>
<tbody>
<tr>
<td>● How can we use arrays to demonstrate the difference between prime and composite numbers?</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Common Misconceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>● Students believe 1 is a prime number.</td>
</tr>
<tr>
<td>● Students believe that since 2 is even it is a composite number.</td>
</tr>
</tbody>
</table>
### Understanding the Standard

- Natural numbers are the counting numbers starting at one.
- A prime number is a natural number, other than one, that has exactly two different factors, one and the number itself.
- A composite number is a natural number that has factors other than one and itself.
- The number one is neither prime nor composite because it has only one set of factors and both factors are one.
- The prime factorization of a number is a representation of the number as the product of its prime factors. For example, the prime factorization of 18 is $2 \times 3 \times 3$.
- Prime factorization concepts can be developed by using factor trees.
- Prime or composite numbers can be represented by rectangular models or rectangular arrays on grid paper. A prime number can be represented by only one rectangular array (e.g., seven can be represented by a $7 \times 1$ and a $1 \times 7$). A composite number can always be represented by two or more rectangular arrays (e.g., nine can be represented by a $9 \times 1$, a $1 \times 9$, or a $3 \times 3$).
- Divisibility rules are useful tools in identifying prime and composite numbers.

### Essential Knowledge and Skills

- The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to:
  - Identify prime numbers less than or equal to 100. (a)
  - Identify composite numbers less than or equal to 100. (a)
  - Demonstrate with concrete or pictorial representations and explain orally or in writing why a number is prime or composite. (a)
  - Identify which numbers are even or odd. (b)
  - Demonstrate with concrete or pictorial representations and explain orally or in writing why a number is even or odd. (b)
  - Demonstrate with concrete or pictorial representations and explain orally or in writing why the sum or difference of two numbers is even or odd. (b)
Odd and even numbers can be explored in different ways (e.g., dividing collections of objects into two equal groups or pairing objects). When pairing objects, the number of objects is even when each object has a pair or partner. When an object is left over, or does not have a pair, then the number is odd.

Students should use manipulatives (e.g., base-ten blocks, cubes, tiles, hundreds board, etc.) to explore and categorize numbers into groups of odd or even.

Examples of ways to use manipulatives to show even and odd numbers may include (but are not limited to):
- for an even number, such as 12, six pairs of counters can be formed with no remainder, or two groups of six counters can be formed with no remainder; and
- for an odd number, such as 13: (a) six pairs of counters can be formed with one counter remaining, or (b) two groups of six counters can be formed with one counter remaining.

Students should use rules to categorize numbers into groups of odd or even. Rules can include:
- An odd number does not have two as a factor and is not divisible by two.
- The sum of two even numbers is even.
- The sum of two odd numbers is even.
- The sum of an even number and an odd number is odd.
- Even numbers have an even number or zero in the ones place.
- Odd numbers have an odd number in the ones place.
- An even number has two as a factor and is divisible by two.
- The product of two even numbers is even.
- The product of two odd numbers is odd.
- The product of an even number and an odd number is even.

● Essential Questions

Common Misconceptions
Richmond Public Schools

Curriculum Framework

Grade 5

- How are the four basic operations related to one another?
- What situations call for the computation of sums? …differences? …products? …quotients? …or a combination of operations?
- How does the context of a problem situation determine how to represent a remainder in division?
- How do we determine whether it is more appropriate to estimate the solutions to problems or to compute the exact answer?
- What determines a reasonable estimation for a given situation?
- How is estimation used to check the reasonableness of the computation involved in solving a problem?
- What are efficient methods for finding sums, differences, products, and quotients? How are the different methods related? How do you determine which strategy you want to use?

- Students may rely on “clue words” to determine if a practical problems involves addition, subtraction, multiplication, or division.
- When adding or subtracting, students misapply the procedure for regrouping.
- Students may know how to add, subtract, multiply, or divide but fail to understand when to add, subtract, multiply, or divide.
- Students think that division is commutative.
- Students think that the operation that needs to be performed (+, -, x, ÷) is defined by the numbers in the problem.
- Students may not understand how to apply a remainder in a practical problem.

</tr>
<tr>
<td>Apply strategies, including place value and application of the properties of addition and multiplication, to solve single step and multistep practical problems involving addition,</td>
<td></td>
</tr>
</tbody>
</table>
Estimation can be used to determine a reasonable range for
the answer to computation and to verify the reasonableness of
sums, differences, products, and quotients of whole numbers.

The least number of steps necessary to solve a single-step
problem is one.

A multistep problem incorporates two or more operational
steps (operations can be the same or different).

Extensive research has been undertaken over the last several
decades regarding different problem types. Many of these
studies have been published in professional mathematics
education publications using different labels and terminology
to describe the varied problem types.

Students should experience a variety of problem types related
to multiplication and division. Some examples are included in
the following chart:

- Subtraction, multiplication, and division of whole numbers,
  with and without remainders, in which:
  - sums, differences, and products do not exceed five
digits;
  - factors do not exceed two digits by three digits;
  - divisors do not exceed two digits; or
  - dividends do not exceed four digits.

Use the context of a practical problem to interpret the
quotient and remainder.
- Students also need exposure to various types of practical problems in which they must interpret the quotient and
remainder based on the context. The chart below includes one example of each type of problem.

<table>
<thead>
<tr>
<th>MAKING SENSE OF THE REMAINDER IN DIVISION</th>
<th>EXAMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remainder is not needed and can be left over (or discarded).</td>
<td>Bill has 29 pencils to share fairly with 6 friends. How many pencils will each friend receive? 4 pencils with 5 pencils left over</td>
</tr>
<tr>
<td>Remainder is partitioned and represented as a fraction or decimal.</td>
<td>Six friends will share 29 ounces of juice. How many ounces will each person get if all of the juice is shared equally? $\frac{5}{6}$ ounces</td>
</tr>
<tr>
<td>Remainder forces the answer to be increased to the next whole number.</td>
<td>There are 29 people going to the party by car. How many cars will be needed if each car holds 6 people? 5 cars</td>
</tr>
<tr>
<td>Remainder forces the answer to be rounded (giving an approximate answer).</td>
<td>Six children will share a bag of candy containing 29 pieces. About how many pieces of candy will each child get? about 5 pieces of candy</td>
</tr>
</tbody>
</table>

- Investigating arithmetic operations with whole numbers helps students learn about several different properties of arithmetic relationships. These relationships remain true regardless of the numbers.
- Grade five students should explore and apply the properties of addition and multiplication as strategies for solving addition, subtraction, multiplication, and division problems using a variety of representations (e.g., manipulatives, diagrams, and symbols).
- The properties of the operations are “rules” about how numbers work and how they relate to one another. Students at this level do not need to use the formal terms for these properties but should utilize these properties to further develop flexibility and fluency in solving problems. The following properties are most appropriate for exploration at this level:
Richmond Public Schools

Curriculum Framework

Grade 5

- The commutative property of addition states that changing the order of the addends does not affect the sum (e.g., $4 + 3 = 3 + 4$). Similarly, the commutative property of multiplication states that changing the order of the factors does not affect the product (e.g., $2 \times 3 = 3 \times 2$).
- The identity property of addition states that if zero is added to a given number, the sum is the same as the given number. The identity property of multiplication states that if a given number is multiplied by one, the product is the same as the given number.
- The associative property of addition states that the sum stays the same when the grouping of addends is changed (e.g., $15 + (35 + 16) = (15 + 35) + 16$).
- The associative property of multiplication states that the product stays the same when the grouping of factors is changed (e.g., $6 \times (3 \times 5) = (6 \times 3) \times 5$).
- The distributive property states that multiplying a sum by a number gives the same result as multiplying each addend by the number and then adding the products.
  - $3(9) = 3(5 + 4)$
  - $3(54 + 4) = 3 \times 54 + 3 \times 4$
  - $5 \times (3 + 7) = (5 \times 3) + (5 \times 7)$
  - $(2 \times 3) + (2 \times 5) = 2 \times (3 + 5)$
  - $9 \times 23$
    - $9 (20 + 3)$
    - $180 + 27$
    - $207$
  - $34 \times 8$

  c) simplify numerical expressions involving integers.* |

### Essential Questions

<table>
<thead>
<tr>
<th><strong>Essential Questions</strong></th>
<th><strong>Common Misconceptions</strong></th>
</tr>
</thead>
</table>
| ● What situations require computation with decimal numbers?  
● How are operations with decimals similar to or different from operations used with whole numbers?  
● What are the effects of multiplying or dividing a given number (whole number and or decimal number) by a multiple of ten?  
● How can we use models and pictures to demonstrate why multiplication of two numbers does not always result in a larger product?  
● What strategies can be developed to estimate and compute sums, differences, products, and quotients of numbers expressed as decimals?  
● How are estimation skills and computational strategies related? | ● Students misapply the rule of placing the decimal when multiplying. Students may move the decimal a certain number of places from the right instead of from the left.  
● Students may confuse where to place the decimal in the quotient.  
● When dividing in a practical problem, students may confuse which number to use as the divisor and the dividend.  
● Students will be confused which operation to use when solving a practical problem.  
● Students will line up digits and not the decimals when adding and subtracting decimals. |

### Understanding the Standard

<table>
<thead>
<tr>
<th><strong>Understanding the Standard</strong></th>
<th><strong>Essential Knowledge and Skills</strong></th>
</tr>
</thead>
</table>
| ● Addition and subtraction of decimals may be investigated using a variety of models (e.g., 10-by-10 grids, number lines, money). | The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to  
  ● Estimate and determine the product of two numbers in which: |
The base-ten relationships and procedures developed for whole number computation apply to decimal computation, giving careful attention to the placement of the decimal point in the solution.

In cases where an exact product is not required, the product of decimals can be estimated using strategies for multiplying whole numbers, such as front-end and compatible numbers, or rounding. In each case, the student needs to determine where to place the decimal point to ensure that the product is reasonable.

Estimation keeps the focus on the meaning of the numbers and operations, encourages reflective thinking, and helps build informal number sense with decimals. Students can reason with benchmarks to get an estimate without using an algorithm.

Estimation can be used to determine a reasonable range for the answer to computation and to verify the reasonableness of sums, differences, products, and quotients of decimals.

Division is the operation of making equal groups or shares. When the original amount and the number of shares are known, divide to determine the size of each share. When the original amount and the size of each share are known, divide to determine the number of shares. Both situations may be modeled with base-ten manipulatives.

The fair-share concept of decimal division can be modeled, using manipulatives (e.g., base-ten blocks). Multiplication and division of decimals can be represented with arrays,

- the factors do not exceed two digits by two digits (e.g., $2.3 \times 4.5$, $0.08 \times 0.9$, $0.85 \times 2.3$, $1.8 \times 5$); and
- the products do not exceed the thousandths place. (Leading zeroes will not be considered when counting digits.) (a)

Estimate and determine the quotient of two numbers in which
- quotients do not exceed four digits with or without a decimal point;
- quotients may include whole numbers, tenths, hundredths, or thousandths;
- divisors are limited to a single digit whole number or a decimal expressed as tenths; and
- no more than one additional zero will need to be annexed. (a)

Use multiple representations to model multiplication and division of decimals and whole numbers. (a)

Create and solve single-step and multistep practical problems involving addition, subtraction, and multiplication of decimals. (b)

Create and solve single-step practical problems involving division of decimals. (b)
paper folding, repeated addition, repeated subtraction, base-ten models, and area models.

- Students in grade four studied decimals through thousandths and solved practical problems that involved addition and subtraction of decimals. Consideration should be given to creating division problems with decimals that do not exceed quotients in the thousandths. Teachers may desire to work backwards in creating appropriate decimal division problems meeting the parameters for grade five students.

- Examples of appropriate decimal division problems for grade five students include, but are not limited to:
  - 2.38 ÷ 4; 6 ÷ 0.2; 1.78 ÷ 0.5; etc.
  - A scientist collected three water samples from local streams. Each sample was the same size, and she collected 1.35 liters of water in all. What was the volume of each water sample?
  - There are exactly 12 liters of sports drink available to the tennis team. If each tennis player will be served 0.5 liters, how many players can be served?
  - The relay team race is exactly 4.8 miles long. Each person on the team is expected to run 0.8 miles. How many team members will be needed to cover the total distance?

- Division with decimals is performed the same way as division of whole numbers. The only difference is the placement of the decimal point in the quotient.

- When solving division problems, numbers may need to be expressed as equivalent decimals by annexing zeros. This
occurs when a zero must be added in the dividend as a place holder.

- The quotient can be estimated, given a dividend expressed as a decimal through thousandths (and no adding of zeros to the dividend during the division process) and a single-digit divisor.
- Estimation can be used to check the reasonableness of a quotient.
- Division is the inverse of multiplication; therefore, multiplication and division are inverse operations.
- Terms used in division are *dividend*, *divisor*, and *quotient*.

\[
\frac{\text{dividend}}{\text{divisor}} = \text{quotient} \\
\text{dividend} = \text{divisor} \times \text{quotient}
\]

- There are a variety of algorithms for division such as repeated multiplication and subtraction. Experience with these algorithms may enhance understanding of the traditional long division algorithm.

5.6 The student will

a) solve single-step and multistep practical problems involving addition and subtraction with fractions and mixed numbers; and

b) solve single-step practical problems involving multiplication of a whole number, limited to 12 or less, and a proper fraction, with models.*

*On the state assessment, items measuring this objective are assessed without the use of a calculator
### Spiraling Standards

**Spiral Down**

4.5 The student will
- a) determine common multiples and factors, including least common multiple and greatest common factor
- b) add and subtract fractions and mixed numbers having like and unlike denominators; and
- c) estimate and determine quotients of whole numbers, with and without remainders; and
- d) solve single-step and multistep practical problems involving addition, subtraction, and multiplication, and single step practice problems involving division with whole numbers

**Spiral Up**

6.5 The student will
- a) multiply and divide fractions and mixed numbers;
- b) solve single-step and multistep practical problems involving addition, subtraction, multiplication, and division of fractions and mixed numbers; and
- c) solve multistep practical problem involving addition, subtraction, multiplication, and division of decimals

### Essential Questions

- What does it mean to “simplify” a fraction, and why is it important?
- How can we use models to devise strategies for renaming improper fractions as mixed numbers and vice versa?
- How is the understanding of multiples and factors useful in simplifying fractions and mixed numbers?
- How can we use mental models, benchmarks, and approximate decimal equivalents to estimate sums and differences of fractions?
- What strategies can be developed to compute sums and differences with fractions and mixed numbers?
- How are common denominators useful when adding and subtracting fractions?

### Common Misconceptions

- When adding fractions, students may try to add both the numerator and denominator.
- When subtracting fractions, students may not understand which fraction to subtract from because they do not know which fraction is larger.
- When solving subtraction practical problems involving a whole number and a fraction, students may not understand and apply the concept of a whole number as a fraction. For example, $10 - 6 \frac{5}{7} = 9 \frac{2}{7} - 6 \frac{5}{7}$
- Students think that multiplying always gives them a larger number.
- When simplifying an answer, students do not use the greatest common factor and fail to simplify the fraction completely.
- A fraction can be expressed in simplest form (simplest equivalent fraction) by dividing the numerator and denominator by their greatest common factor.
- When the numerator and denominator have no common factors other than one, then the fraction is in simplest form.
- Fractions having like denominators have the same meaning as fractions having common denominators.
- Addition and subtraction with fractions and mixed numbers can be modeled using a variety of concrete and pictorial representations.
- Estimation keeps the focus on the meaning of the numbers and operations, encourages reflective thinking, and helps build informal number sense with fractions. Students can reason with benchmarks to get an estimate without using an algorithm. Estimation can be used to check the reasonableness of an answer.
- A mixed number has two parts: a whole number and a fraction. The value of a mixed number is the sum of its two parts.
- A unit fraction is a fraction in which the numerator is one.
- Models for representing multiplication of fractions may include arrays, paper folding, repeated addition, fraction strips or rods, pattern blocks, or area models.
- Students should begin exploring multiplication with fractions by solving problems that involve a whole number and a unit fraction.
- When multiplying a whole number by a fraction such as $6 \times \frac{1}{2}$, the meaning is the same as with multiplication of whole numbers: six groups the size of $\frac{1}{2}$ of the whole.

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to:

- Solve single-step and multistep practical problems involving addition and subtraction with fractions (proper or improper) having like and unlike denominators and/or mixed numbers. Denominators in the problems should be limited to 12 or less (e.g., $\frac{5}{8} + \frac{1}{4}$, $\frac{5}{6} - \frac{2}{3}$, $3 \frac{3}{4} + 2 \frac{5}{12}$) and answers should be expressed in simplest form. (a)
- Solve single-step practical problems involving multiplication of a whole number, limited to 12 or less, and a proper fraction (e.g., $6 \times \frac{1}{3}$, $\frac{1}{4} \times 8$, $9 \times \frac{2}{3}$), with models. The denominator will be a factor of the whole number and answers should be expressed in simplest form. (b)
- Apply the inverse property of multiplication in models. (For example, use a visual fraction model to represent $\frac{4}{4}$ or 1 as the product of $4 \times \frac{1}{4}$). (b)
• When multiplying a fraction by a whole number such as $\frac{1}{2} \times 6$, we are trying to determine a part of the whole (e.g., one-half of six).

• The inverse property of multiplication states that every number has a multiplicative inverse and the product of multiplicative inverses is 1 (e.g., 5 and $\frac{1}{5}$ are multiplicative inverses because $5 \times \frac{1}{5} = 1$). The multiplicative inverse of a given number can be called the reciprocal of the number. Students at this level do not need to use the term for the properties of the operations.

• Multiplying a whole number by a unit fraction can be related to dividing the whole number by the denominator of the fraction. For example, $\frac{1}{2}$ of 6 is equivalent to 2. This understanding forms a foundation for learning how to multiply a whole number by a proper fraction.

• At this level, students will use models to solve problems that involve multiplication of a whole number, limited to 12 or less, and a proper fraction where the denominator is a factor
of the whole number. For example, a model for $\frac{3}{4} \times 8$ or $8 \times \frac{3}{4}$ shows that the answer is three groups of $\frac{1}{4} \times 8$.

- Examples of problems grade five students should be able to solve include, but are not limited to the following:
  - If nine children each bring $\frac{1}{3}$ cup of candy for the party, how many thirds will there be? What will be the total number of cups of candy?
  - If it takes $\frac{1}{4}$ cup of ice cream to fill an ice cream cone, how much ice cream will be needed to fill eight cones?
- Resulting fractions should be expressed in simplest form.
- Problems where the denominator is not a factor of the whole number (e.g., $\frac{1}{8} \times 6$ or $6 \times \frac{1}{8}$) will be a focus in grade six.

The Hershey’s Milk Chocolate Bar Fractions Book by Jerry Pallotta
After the initial read, the story can be used again for practicing adding and subtracting fractions. On each page, teacher will have students roll a dice twice to create a fraction (lower number serves as the numerator and higher number serves as the denominator) to be added or subtracted from the fraction on the page. The teacher can also ask real world questions about adding or subtracting pieces to make the practice more meaningful.

| ● An expression is a representation of a quantity. It is made up of numbers, variables, computational symbols, and grouping symbols. It does not have an equal symbol (e.g., $15 \times 12$).  
● Expressions containing more than one operation are simplified by using the order of operations.  
● The order of operations is a convention that defines the computation order to follow in simplifying an expression. It ensures that there is only one correct value.  
● The order of operations is as follows:  
  - First, complete all operations within grouping symbols. If there are grouping symbols within other grouping symbols, do the innermost operation first. (Students in grade five are not expected to simplify expressions having parentheses within other grouping symbols.) | The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to  
● Use the order of operations to simplify whole number numerical expressions, limited to addition, subtraction, multiplication, and division. Expressions may contain parentheses.  
● Given a whole number numerical expression involving more than one operation, describe which operation is completed first, which is second, etc. |
Richmond Public Schools
Curriculum Framework
Grade 5

- If there are multiple operations within the parentheses, apply the order of operations.
- Second, evaluate all exponential expressions. (Students in grade five are not expected to simplify expressions with exponents.)
- Third, multiply and/or divide in order from left to right.
- Fourth, add and/or subtract in order from left to right.

</tr>
</tbody>
</table>
**Richmond Public Schools**

**Curriculum Framework**

**Grade 5**

- Students should use manipulatives to discover the formulas for the area of a right triangle and volume of a rectangular solid.
  - Area of a right triangle = $\frac{1}{2} \text{ base} \times \text{height}$
  - Volume of a rectangular solid = length $\times$ width $\times$ height

- Students would benefit from opportunities that include the use of benchmark fractions (e.g., $\frac{1}{2}$, $\frac{1}{4}$) in determining perimeter.

- The area of a rectangle can be determined by multiplying the length of the base by the length of the height.

- The diagonal of the rectangle shown divides the rectangle in half creating two right triangles. The legs of the right triangles are congruent to the side lengths of the rectangle. The representation illustrates that the area of each right triangle is half the area of the rectangle. Exploring the decomposition of shapes helps students develop algorithms for determining area of various shapes (e.g., area of a triangle is $\frac{1}{2} \times \text{base} \times \text{height}$).

- The distance from the top of the right triangle to its base is called the height of the triangle.

<table>
<thead>
<tr>
<th>Develop a procedure for determining the area of a right triangle using only whole number measurements given in metric or U.S. Customary units, and record the solution with the appropriate unit of measure (e.g., 12 square inches). (a)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Estimate and determine the area of a right triangle, with diagrams, when the base and the height are given. (a)</td>

<td>Describe practical situations where perimeter, area, and volume are appropriate measures to use, and justify orally or in writing. (b)</td>
</tr>
<tr>
<td>Identify whether the application of the concept of perimeter, area, or volume is appropriate for a given situation. (b)</td>
</tr>
</tbody>
</table>
Two congruent right triangles can always be arranged to form a square or a rectangle.

To develop the formula for determining the volume of a rectangular prism, volume = length × width × height, students will benefit from experiences filling rectangular prisms (e.g., shoe boxes, cereal boxes) with cubes by first covering the bottom of the box and then building up the layers to fill the entire box.

Strand: Measurement and Geometry

5.9 The student will
   a) given the equivalent measure of one unit, identify equivalent measurements within the metric system; and
   b) solve practical problems involving length, mass, and liquid volume using metric units.

Suggested Pacing
3rd Nine Weeks

Related Spiraling Standards
### Spiral Down

4.8 The student will
a) estimate and measure length and describe the result in U.S. Customary and metric units;
b) estimate and measure weight/mass and describe the result in U.S. Customary and metric units;
c) given the equivalent measure of one unit, identify equivalent measures of length, weight/mass, and liquid volume between units within the U.S. Customary system; and
d) solve practical problems that involve length, weight/mass, and liquid volume in U.S. Customary units.

### Essential Questions

- Why are all measurements approximations? How does the selection of an appropriate unit of measurement and measurement tool affect the precision of the solution to problems involving measurement?
- What tools are used in linear measurement? …measurement of weight/mass? …measurement of liquid volume? …measurement of temperature? How does one determine which is appropriate to use?
- How do the units within a system relate to each other?
- How can we use benchmarks to help us estimate measurements of length, weight/mass, and liquid volume in metric units?

### Understanding the Standard

- Length is the distance between two points along a line.
- Metric units for measurement of length include millimeters, centimeters, meters, and kilometers. Appropriate measuring devices include centimeter ruler, meter stick, and tape measure.

### Essential Knowledge and Skills

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to

- Given the equivalent measure of one unit, identify equivalent measurements within the metric system for the following:
Weight and mass are different. Mass is the amount of matter in an object. Weight is determined by the pull of gravity on the mass of an object. The mass of an object remains the same regardless of its location. The weight of an object changes depending on the gravitational pull at its location. In everyday life, most people are actually interested in determining an object’s mass, although they use the term weight (e.g., “How much does it weigh?” versus “What is its mass?”).

Balances are appropriate measuring devices to measure mass in U.S. Customary units (ounces, pounds) and metric units (grams, kilograms).

Metric units to measure liquid volume (capacity) include milliliters and liters.

Practical experience measuring familiar objects helps students establish benchmarks and facilitates students’ ability to use the appropriate units of measure to make estimates.

Students at this level will be given the equivalent measure of one unit when asked to determine equivalencies between units in the metric system. An example can be found below.

Students will be told 1 kilometer is equivalent to 1,000 meters and then will be asked to apply that relationship to determine:
- the number of meters in 3.5 kilometers;
- the number of kilometers equal to 2,100 meters; or
- Seth ran 2.78 kilometers on Saturday. How many meters are equivalent to 2.78 kilometers?

Estimate and measure to solve practical problems that involve metric units:
- length (millimeters, centimeters, meters, and kilometers);
- mass (grams and kilograms); and
- liquid volume (milliliters and liters). (a)

| 4.10 The student will  
  a) identify and describe points, lines, line segments, rays, and angles, including endpoints and vertices | 6.7 The student will  
  a) derive $\pi$;  
  b) solve problems, including practical problems, involving circumference and area of a circle; and  
  c) solve problems, including practical problems, involving area and perimeter of triangles and rectangles. |

#### Essential Questions

- How is a chord related to a diameter?  
- How does diameter relate to radius?  
- How does radius relate to circumference? How does diameter relate to circumference?  
- How is circumference related to perimeter?

#### Common Misconceptions

- Students have difficulty remembering the definitions of chord, diameter, radius, and circumference.  
- Students do not understand that the diameter is a type of chord and believe that a chord cannot pass through the center.

#### Understanding the Standard

- A circle is a set of points in a plane that are the same distance from a point called the **center**.  
- A chord is a line segment connecting any two points on a circle. A chord may or may not go through the center of a circle. The diameter is the longest chord of a circle.  
- A diameter is a chord that goes through the center of a circle. The length of the diameter of a circle is twice the length of the radius.

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to

- Identify and describe the diameter, radius, chord, and circumference of a circle.  
- Investigate and describe the relationship between  
  - diameter and radius;  
  - diameter and chord;  
  - radius and circumference; and
**Richmond Public Schools**

**Curriculum Framework**  
**Grade 5**

- A radius is a line segment joining the center of a circle to any point on the circle. Two radii end-to-end form a diameter of a circle.
- Circumference is the distance around or “perimeter” of a circle. An approximation for circumference is about three times the diameter of a circle. An approximation for circumference is about six times the radius of a circle.

### Essential Questions

- What is meant by elapsed time?
- When might we need to find elapsed time?
- What strategies can we use to find elapsed time?

### Common Misconceptions

- Students overgeneralize base-10 and apply it to time inappropriately.

### Understanding the Standard

- Elapsed time is the amount of time that has passed between two given times.
- Elapsed time can be found by counting on from the beginning time or counting back from the ending time.

### Essential Knowledge and Skills

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to

- Solve practical problems related to elapsed time in hours and minutes within a 24-hour period:
  - when given the beginning time and the ending time, determine the time that has elapsed;
  - when given the beginning time and amount of elapsed time in hours and minutes, determine the ending time; or
  - when given the ending time and the elapsed time in hours and minutes, determine the beginning time.

<tbody>
<tr>
<td>4.10 The Student will</td>
<td>6.9 The student will determine congruence of segments, angles, and polygons</td>
</tr>
<tr>
<td>a) identify and describe points, lines, line segments, rays, and angles, including endpoints and vertices; and</td>
<td></td>
</tr>
<tr>
<td>b) identify and describe intersecting, parallel, and perpendicular lines.</td>
<td></td>
</tr>
</tbody>
</table>

#### Essential Questions

- How does angle measurement differ from linear measurement?
- How can we use benchmark angle measurements (e.g., 90°, 180°) to determine the measurement of other angles?
- How is a protractor or an angle ruler used to measure?
- How can visualizing a circle folded into halves and quarters help us classify angles?

#### Common Misconceptions

- Students do not line up the vertex of the angle with the center mark of the protractor.
- Students do not line up the zero edge of the protractor with the ray of the angle.
- Students read the wrong number on the protractor when finding the measure of an angle.
- Students confuse the terms acute angle, obtuse angle, right angle, and straight angle.

#### Understanding the Standard

- Angles can be classified as right, acute, obtuse, or straight according to their measures.
- Angles are measured in degrees. A degree is \( \frac{1}{360} \) of a complete rotation of a full circle. There are 360 degrees in a circle.

#### Essential Knowledge and Skills

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to

- Classify angles as right, acute, obtuse, or straight.
- Identify the appropriate tools (e.g., protractor and straightedge or angle ruler as well as available software) used to measure and draw angles.
To measure the number of degrees in an angle, use a protractor or an angle ruler.

A right angle measures exactly 90 degrees.

An acute angle measures greater than zero degrees but less than 90 degrees.

An obtuse angle measures greater than 90 degrees but less than 180 degrees.

A straight angle measures exactly 180 degrees.

Before measuring an angle, students should first compare it to a right angle to determine whether the measure of the angle is less than or greater than 90 degrees.

Students should recognize angle measure as additive. When an angle is decomposed into nonoverlapping parts, the angle measure of the whole is the sum of the angle measures of the parts.

Students should understand how to work with a protractor or angle ruler as well as available computer software to measure and draw angles and triangles.

- Measure right, acute, obtuse, and straight angles, using appropriate tools, and identify their measures in degrees.
- Solve addition and subtraction problems to determine unknown angle measures on a diagram in practical problems.

</tr>
<tr>
<td>4.12 The student will classify quadrilaterals as parallelograms, rectangles, squares, rhombi, and/or trapezoids.</td>
<td></td>
</tr>
</tbody>
</table>

### Essential Questions

- How are angle properties used to classify triangles?
- How are side lengths used to classify triangles?
- How does the sum of the interior angles of a triangle help you determine an unknown angle measure?
- How can you use models to prove that the sum of the interior angles of a triangle is 180°?
- How are geometric markings used to identify congruent sides and right angles of triangles?

### Common Misconceptions

- Students confuse the definitions of the different types of triangles.
- Students do not understand that a triangle can be classified in more than one way.
- Students may not know the measurement of the interior angles of a triangle.

### Understanding the Standard

- Angles can be classified as right, acute, obtuse, or straight according to their measures.
- A triangle can be classified as right, acute, or obtuse according to the measure of its largest angle.
- Triangles may also be classified according to the measure of their sides, e.g., scalene (no sides congruent), isosceles (at least two sides congruent) and equilateral (all sides congruent).

### Essential Knowledge and Skills

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to

- Classify triangles as right, acute, or obtuse. (a)
- Classify triangles as equilateral, scalene, or isosceles. (a)
- Compare and contrast the properties of triangles. (a)
- Identify congruent sides and right angles using geometric markings to denote properties of triangles. (a)
• An equilateral triangle (with three congruent sides) is a special case of an isosceles triangle (which has at least two congruent sides).

• Triangles can be classified by the measure of their largest angle and by the measure of their sides (i.e., an isosceles right triangle).

![Isosceles Right Triangle]

• Congruent sides are denoted with the same number of hatch (or hash) marks on each congruent side.

• A right angle measures exactly 90 degrees.

• An acute angle measures greater than zero degrees but less than 90 degrees.

• An obtuse angle measures greater than 90 degrees but less than 180 degrees.

• A straight angle measures exactly 180 degrees.

• A right triangle has one right angle.

• An obtuse triangle has one obtuse angle.

• An acute triangle has three acute angles.

• A scalene triangle has no congruent sides.

• An isosceles triangle has at least two congruent sides.

• Use models to prove that the sum of the interior angles of a triangle is 180 degrees, and use that relationship to determine an unknown angle measure in a triangle. (b)
Richmond Public Schools
Curriculum Framework
Grade 5

- An equilateral triangle has three congruent sides. All angles of an equilateral triangle are congruent and measure 60 degrees.

<td>6.9 The student will determine congruence of segments, angles, and polygons</td>
</tr>
</tbody>
</table>

### Essential Questions

- How can transformations help us understand congruency?
- How can we recognize and apply transformations (translation, reflection, and rotation)?
- How can we predict and explain the results of combining and subdividing polygons into other polygons?

### Common Misconceptions

- Students do not understand that once a transformation has been applied to a polygon, the resulting polygon is congruent.
- Students confuse the terms translation, reflection, and rotation.
- Students have difficulty subdividing polygons and identifying which polygons make up a larger polygon.

### Understanding the Standard

- A transformation of a figure (preimage) changes the size, shape, or position of the figure to a new figure (image).

### Essential Knowledge and Skills

The student will use problem solving, mathematical communication, mathematical reasoning, connections and representation to
Richmond Public Schools

Curriculum Framework
Grade 5

- Transformations can be explored using mirrors, paper folding, and tracing.
- Congruent figures have the same size and shape.
- A translation is a transformation in which an image is formed by moving every point on the preimage the same distance in the same direction.
- A reflection is a transformation in which an image is formed by reflecting the preimage over a line called the line of reflection. All corresponding points in the image and preimage are equidistant from the line of reflection.
- A rotation is a transformation in which an image is formed by rotating the preimage about a point called the center of rotation. The center of rotation may or may not be on the preimage.
- The resulting figure of a translation, reflection, or rotation is congruent to the original figure.
- The orientation of figures does not affect congruency or noncongruency.
- A polygon is a closed plane figure composed of at least three line segments that do not cross.
- Two or more polygons can be combined to form a new polygon. Students should be able to identify the figures that have been combined.
- A polygon that can be divided into more than one basic figure is said to be a composite figure (or shape). Students should understand how to divide a polygon into familiar figures.

- Apply transformations to polygons in order to determine congruence. (a)
- Recognize that translations, reflections, and rotations preserve congruency. (a)
- Identify the image of a polygon resulting from a single transformation (translation, reflection, or rotation). (a)
- Investigate and describe the results of combining and subdividing polygons. (b)
- Compare and contrast the characteristics of a given polygon that has been subdivided with the characteristics of the resulting parts. (b)
This diagonal of the rectangle above subdivides the rectangle in half and creates two right triangles. The figure can also be formed by combining two right triangles that are congruent. The resulting figure shows that the legs of the right triangles are congruent to the sides of the rectangle. The representation illustrates that the area of each right triangle is half the area of the rectangle. Exploring decomposition of shapes helps students develop algorithms for determining area of various shapes (e.g., area of a triangle is \( \frac{1}{2} \times \text{base} \times \text{height} \)).

- Congruent sides are denoted with the same number of hatch (or hash) marks on each congruent side. For example, a side on a polygon with two hatch marks is congruent to the side with two hatch marks on a congruent polygon or within the same polygon.

</thead>
<tbody>
<tr>
<td>Essential Questions</td>
<td>Common Misconceptions</td>
</tr>
<tr>
<td>● How can we construct a sample space to show all of the possible combinations (outcomes)?</td>
<td>● Students only see the most obvious possibilities.</td>
</tr>
</tbody>
</table>
### Understanding the Standard

- A spirit of investigation and experimentation should permeate probability instruction, where students are actively engaged in explorations and have opportunities to use manipulatives, tables, tree diagrams, and lists.
- Probability is the measure of likelihood that an event will occur. An event is a collection of outcomes from an investigation or experiment.
- The probability of an event can be expressed as a fraction, where the numerator represents the number of favorable outcomes and the denominator represents the total number of possible outcomes. If all the outcomes of an event are equally likely to occur, the probability of the event is equal to:

  
  \[
  \text{number of favorable outcomes} \quad \frac{\text{total number of possible outcomes}}{}
  \]

- Probability is quantified as a number between zero and one. An event is “impossible” if it has a probability of zero (e.g., the probability that the month of April will have 31 days). An event is “certain” if it has a probability of one (e.g., the

### Essential Knowledge and Skills

The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to

- Construct a sample space, using a tree diagram to identify all possible outcomes.
- Construct a sample space, using a list or chart to represent all possible outcomes.
- Determine the probability of an outcome by constructing a sample space. The sample space will have a total of 24 or fewer equally likely possible outcomes.
- Determine the number of possible outcomes by using the Fundamental (Basic) Counting Principle.
probability that if today is Thursday then tomorrow will be Friday).

- When a probability experiment has very few trials, the results can be misleading. The more times an experiment is done, the closer the experimental probability comes to the theoretical probability (e.g., a coin lands heads up half of the time).

- Students should have opportunities to describe in informal terms (i.e., impossible, unlikely, equally likely, likely, and certain) the degree of likelihood of an event occurring. Activities should include practical examples.

- A sample space represents all possible outcomes of an experiment. The sample space may be organized in a list, chart, or tree diagram.

- Tree diagrams can be used to illustrate all possible outcomes in a sample space. For example, how many different outfit combinations can you make from two shirts (red and blue) and three pants (black, white, khaki)? The sample space displayed in a tree diagram would show the outfit combinations: red-black; red-white; red-khaki; blue-black; blue-white; blue-khaki. Exploring the use of tree diagrams for modeling combinations helps students develop the Fundamental Counting Principle. For this problem, applying the Fundamental Counting Principle shows there are $2 \times 3 = 6$ outcomes.

- The Fundamental (Basic) Counting Principle is a computational procedure to determine the total number of possible outcomes when there are multiple choices or several events. It is the product of the number of outcomes for each choice or event that can be chosen individually. For example, the possible final outcomes or outfits of four shirts (green,
yellow, blue, red), two shorts (tan or black), and three shoes (sneakers, sandals, flip flops) is \(4 \times 2 \times 3 = 24\) outfits.

</tr>
<tr>
<td>Investigations that support collecting data can be brief class surveys or more extended projects taking many days.</td>
<td>Organize the data into a chart or table. (a)</td>
</tr>
<tr>
<td>Through experiences displaying data in a variety of graphical representations, students learn to select an appropriate representation (i.e., a representation that is more helpful in analyzing and interpreting the data to answer questions and make predictions).</td>
<td>Represent data in a line plot. Line plots will have no more than 30 data points. (a)</td>
</tr>
<tr>
<td>There are two types of data: categorical and numerical. Categorical data can be sorted into groups or categories while.</td>
<td>Represent data in a stem-and-leaf plot where the stem is listed in ascending order and the leaves are in ascending order, with or without commas between leaves. Stem-and-leaf plots will be limited to no more than 30 data points. (a)</td>
</tr>
</tbody>
</table>

- Students can easily miss or forget a data point when building a stem and leaf plot or a line plot.
numerical data are values or observations that can be measured. For example, types of fish caught would be categorical data while weights of fish caught would be numerical data. While students need to be aware of the differences, they do not have to know the terms for each type of data.

- A line plot shows the frequency of data on a number line. Line plots are used to show the spread of the data and quickly identify the range and mode.

- A stem and leaf plot uses columns to display a summary of discrete numerical data while maintaining the individual data points. A stem-and-leaf plot displays data to show its shape and distribution.

- Interpret data by making inferences from line plots and stem-and-leaf plots. (b)
- Compare data represented in a line plot with the same data represented in a stem-and-leaf plot. (c)
The data are organized from least to greatest.

Each value is separated into a stem and a leaf (e.g., two-digit numbers are separated into stems (tens) and leaves (ones)).

The stems are listed vertically from least to greatest with a line to their right. The leaves are listed horizontally, also from least to greatest, and can be separated by spaces or commas. Every value is recorded, regardless of the number of repeats. No stem can be skipped. For example, in the stem and leaf plot above, there are no data for the stem 5; 5 should be listed showing no leaves.

A key is included to explain how to read the plot.
Different situations call for different types of graphs. The way data are displayed is often dependent upon what someone is trying to communicate.

Comparing different types of representations (e.g., charts, graphs, line plots, etc.) provides students an opportunity to learn how different graphs can show different aspects of the same data. Following construction of representations, students benefit from discussions around what information each representation provides.

Tables or charts organize the exact data and display numerical information. They do not show visual comparisons, which generally means it takes longer to understand or to examine trends.

Bar graphs can be used to compare data easily and see relationships. They provide a visual display comparing the numerical values of different categories. The scale of a bar graph may affect how one perceives the data.

Comparisons, predictions and inferences are made by examining characteristics of a data set displayed in a variety of graphical representations to draw conclusions.

Sample questions that could be explored in comparing different representations such as a chart to a line plot and a stem-and-leaf plot could include: In which representation can you quickly identify the mode? The range? What predictions can you make?

Richmond Public Schools

Curriculum Framework

**Grade 5**

- Lesson 18.1 Data from Surveys
- Lesson 18.4 Stem-and-Leaf Plots
- Differentiated Center Activities: 18.1, 18.4

**Eureka Math**

5.16 a, b, c
- GRADE 3 MODULE 6: Collecting and Displaying Data
- GRADE 3 MODULE 7 Lesson 22: Use a line plot to record the number of rectangles constructed in Lessons 20 and 21.

**Note:** Supplemental material is necessary to address stem and leaf plots

**Notes**
- Interactive Notebook Math Grade 5
  - Line Plots pages 54-55
  - Stem-and-Leaf Plots pages 56-57

**Resources**
- **Print**
    - Line Plots, Chapter 18, pp. 389-390
  - [Domino Line Plot Activity](#)
  - [Grade 5 Line Plot Graphing Sort](#)
  - [Grade 5 Stem and Leaf Plot Graphing Sort](#)
  - [Stem and Leaf Plot Notes](#)
  - [Grade 5 Math VDOE Sample Items](#)
  - [Grade 5 Line Plot Stations](#)
  - [Grade 5 Math Junk Mail Graph Project](#)
  - [Grade 5 Line Plot Summary](#)
Richmond Public Schools

Curriculum Framework

Grade 5

- Grade 5 Line Plot Cards
- Grade 5 VDOE Sample Items Graphing
- Grade 5 What’s My Name Worth Stem Leaf Model Lesson

**Technology-based**
- Gizmo: Reaction Time 2 (a)
- Gizmo: Stem and Leaf Plots (c)
- Study Jams: Stem-and-Leaf Plots (a, b)

**Station Activities**

**Foam Cubes (1-6):** Using foam cubes, students will build a data set of 15 numbers by rolling 2 dice at a time and will create a stem and leaf plot using this data. (a)

**Graphing Mats:** Using dry erase graphing mats, students will create a line plot illustrating the data given. (a)

### Cross-Curricular Connections

<table>
<thead>
<tr>
<th>Essential Questions</th>
<th>Common Misconceptions</th>
</tr>
</thead>
</table>
| ● How are the mean, median, mode, and range of a set of data computed? How can they be determined from various data displays: tables? graphs? stem-and-leaf plots?  
● How can we describe the similarities and differences of mean, median, mode, and range of the same set of data?  
● How are the statistics—mean, median, mode, and/or range—affect ed by outliers in a data set?  
● How can we use objects to demonstrate the idea of the mean as a fair share?  
● Why are the mean, median, and mode all considered measures of center? What are the advantages/disadvantages of each for describing a data set? | ● Students may confuse the difference between mean, median, and mode.  
● When there is an even amount of items in a data set, students may be confused on how to find the median. |

<table>
<thead>
<tr>
<th>Understanding the Standard</th>
<th>Essential Knowledge and Skills</th>
</tr>
</thead>
</table>
| ● Statistics is the science of conducting studies to collect, organize, summarize, analyze, and draw conclusions from data.  
● Students need to learn more than how to identify the mean, median, mode, and range of a set of data. They need to build an understanding of what the measure tells them about the data, and see those values in the context of other characteristics of the data in order to best describe the results.  
● A measure of center is a value at the center or middle of a data set. Mean, median, and mode are measures of center.  
● The mean, median, and mode are three of the various ways that data can be analyzed. | The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to  
● Describe and determine the mean of a group of numbers representing data from a given context as a measure of center. (a, d)  
● Describe and determine the median of a group of numbers representing data from a given context as a measure of center. (a, d)  
● Describe and determine the mode of a group of numbers representing data from a given context as a measure of center. (a, d)  
● Describe mean as fair share. (b) |
Richmond Public Schools

Curriculum Framework

Grade 5

- The mean, median, and mode are referred to as types of averages. The term arithmetic average can be used when referring to the mean.
- Mean represents a fair share concept of the data. Dividing the data constitutes a fair share. This idea of dividing as sharing equally should be demonstrated visually and with manipulatives to develop the foundation for the arithmetic process. The arithmetic way is to add all of the data points and then divide by the number of data points to determine the arithmetic average or mean.
- The median is the middle value of a data set in ranked order. Given an odd number of pieces of data, the median is the middle value in ranked order. If there is an even number of pieces of data, the median is the arithmetic average of the two middle values.
- The mode is the piece of data that occurs most frequently in the data set. There may be one, more than one, or no mode in a data set. Students should order the data from least to greatest so they can better determine the mode.
- The range is the spread of a set of data. The range of a set of data is the difference between the greatest and least values in the data set. It is determined by subtracting the least number in the data set from the greatest number in the data set. An example is ordering test scores from least to greatest: 73, 77, 84, 87, 89, 91, 94. The greatest score in the data set is 94 and the least score is 73, so the least score is subtracted from the greatest score or 94 - 73 = 21. The range of these test scores is 21.

<td>● Students may not make connections between concrete materials and numerical representations (number sequence, and tables.)</td>
</tr>
<tr>
<td>● How are tables, graphs, and mathematical expressions used to represent relationships in patterns?</td>
<td>● Students may confuse growing patterns with repeating patterns and if not given many opportunities to explore patterns using concrete materials and calculators, they may not gain understanding of these patterns.</td>
</tr>
<tr>
<td>● How can we identify, describe and extend single-operation input and output rules?</td>
<td>● Students may struggle with finding an unknown term in a pattern when it is not the very next item. Students often give the next item in a pattern when asked to find the 12th or 15th item.</td>
</tr>
<tr>
<td>● How can we find the rule in a list or table?</td>
<td>● When working with input/output tables, students may have difficulty figuring out the unknown value.</td>
</tr>
<tr>
<td>● How can pattern identification be used to solve problems?</td>
<td>● Students may not recognize that the rule in an input/output table is read across the input/output and not from output to</td>
</tr>
</tbody>
</table>
Richmond Public Schools

Curriculum Framework

*Grade 5*

<table>
<thead>
<tr>
<th>Understanding the Standard</th>
<th>Essential Knowledge and Skills</th>
</tr>
</thead>
<tbody>
<tr>
<td>● Mathematical relationships exist in patterns. There are an infinite number of patterns.</td>
<td>The student will use problem solving, mathematical communication, mathematical reasoning, connections, and representations to</td>
</tr>
<tr>
<td>● Patterns and functions can be represented in many ways and described using words, tables, and symbols.</td>
<td>● Identify, create, describe, and extend patterns using concrete materials, number lines, tables, or pictures.</td>
</tr>
<tr>
<td>● Students need experiences exploring growing patterns using concrete materials and calculators. Calculators are valuable tools for generating and analyzing patterns. The emphasis is not on computation but on identifying and describing patterns.</td>
<td>● Describe and express the relationship found in patterns, using words, tables, and symbols.</td>
</tr>
<tr>
<td>● Patterns at this level may include: addition, subtraction, or multiplication of whole numbers; addition or subtraction of fractions (with denominators 12 or less); and decimals expressed in tenths or hundredths. Several sample numerical patterns are included below:</td>
<td>● Solve practical problems that involve identifying, describing, and extending single-operation input and output rules (limited to addition, subtraction and multiplication of whole numbers; addition and subtraction of fractions, with denominators of 12 or less; and addition and subtraction of decimals expressed in tenths or hundredths).</td>
</tr>
<tr>
<td>• 1, 2, 4, 7, 11, 16, …;</td>
<td>● Identify the rule in a single-operation numerical pattern found in a list or table (limited to addition, subtraction and multiplication of whole numbers; addition and subtraction of fractions, with denominators of 12 or less; and addition and subtraction of decimals expressed in tenths or hundredths).</td>
</tr>
</tbody>
</table>

● When students are looking at growing patterns with objects, they may not recognize how the pattern is growing and may need manipulatives to make the pattern.

● Students often assume that if a rule works for the first two numbers in a pattern that it can be applied to the entire pattern. Be sure to check if the pattern keeps working for multiple steps, because 4, 8… could be the beginning of plus 4, or times 2.
• 2, 4, 8, 16, 32, ...;
• 32, 30, 28, 26, 24…;
• 0.15, 0.35, 0.55, 0.75...; and
• $\frac{1}{4}, \frac{3}{4}, 1 \frac{1}{4}, 1 \frac{3}{4} ...$

- Students in grades three and four had experiences working with input/output tables to determine the rule or a missing value. Generalizing patterns to identify rules and applying rules builds the foundation for functional thinking. Sample input/output tables that require determination of the rule or missing terms can be found below:

<table>
<thead>
<tr>
<th>Rule: ?</th>
<th>Rule: ?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input</td>
<td>Output</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>?</td>
</tr>
<tr>
<td>6</td>
<td>12</td>
</tr>
<tr>
<td>?</td>
<td>20</td>
</tr>
</tbody>
</table>

- A numerical expression is a representation of a quantity. It is made up of numbers, variables, and/or computational symbols. It does not have an equal symbol (e.g., $15 \times 12$).
- A verbal expression involving one operation can be represented by a variable expression that describes the relationship. Numbers are used when they are known; variables are used when the numbers are unknown. The example in the table below defines the relationship between the input number and output number as $x + 3$. Students at this level are not expected to write a variable expression to
describe patterns. They might describe the pattern below as $+ 3$ or given any number, add three.

<table>
<thead>
<tr>
<th>$x$</th>
<th>$y$</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>9</td>

</table>

<table>
<thead>
<tr>
<th>Common Misconceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>● Students may be confused why there are not only numbers in a problem.</td>
</tr>
</tbody>
</table>
### Understanding the Standard

- A variable is a symbol that can stand for an unknown number (e.g., \(a + 4 = 6\)) or for a quantity that changes (e.g., the rule or generalization for the pattern for an input/output table such as \(x + 2 = y\)).
- An algebraic expression, an expression with a variable, is like a phrase; a phrase does not have a verb, so an expression does not have an equal symbol (=).
- A verbal expression describing a relationship involving one operation can be represented by an expression with a variable that mathematically describes the relationship. Numbers are used when quantities are known; variables are used when the quantities are unknown. For example, when \(b\) stands for the number of cookies in one full box, “the number of cookies in a full box and four extra” can be represented by \(b + 4\); “three full boxes of cookies” by \(3b\); “the number of cookies each person would receive if a full box of cookies were shared among four people” by \(\frac{b}{4}\).
● An equation is a statement that represents the relationship between two expressions of equal value (e.g., $12 \times 3 = 72 \div 2$).

● A problem situation about two quantities that are equal can be expressed as an equation.

● An equation may contain a variable and an equal symbol ($=$). For example, the sentence, “A full box of cookies and four extra equal 24 cookies.” can be written as $b + 4 = 24$, where $b$ stands for the number of cookies in one full box. “Three full boxes of cookies contain a total of 60 cookies” can be written as $3b = 60$.

● Another example of an equation is $b + 3 = 23$ and represents the answer to the word problem, “How many cookies are in a box if the box plus three more equals 23 cookies?” where $b$ stands for the number of cookies in the box?

● Teachers should consider varying the letters used (in addition to $x$) to represent variables. The symbol $'$ is often used to represent multiplication and can be confused with the variable $x$. In addition to varying the use of letters as variables, this confusion can be minimized by using parentheses [e.g., $4(x) = 20$ or $4x = 20$] or a small dot raised off the line to represent multiplication [4 • $x = 20$].

● By using story problems and numerical sentences, students begin to explore forming equations and representing quantities using variables.
Richmond Public Schools  
Curriculum Framework  
**Grade 5**

- An equation containing a variable is neither true nor false until the variable is replaced with a number and the value of the expressions on both sides are compared.
